SGM66099
Synchronous Step-Up Converter with Ultra Low Quiescent Current

GENERAL DESCRIPTION

The SGM66099 is a synchronous step-up converter with 0.65μA ultra low quiescent current. It is designed for products powered by alkaline battery, NiMH rechargeable battery, Li-Mn battery or rechargeable Li-Ion battery, for which high efficiency under light load condition is critical to achieve long battery life operation.

The SGM66099 step-up converter only consumes 0.65μA quiescent current under light load condition and can achieve up to 75% efficiency at 10μA load with fixed output voltage version. It can also support up to 300mA output current from 3.3V to 5V conversion, and achieve up to 93% efficiency at 200mA load.

The SGM66099 also offers both down mode and pass-through operation for different applications. In down mode, the output voltage can still be regulated at target value even when input voltage is higher than output voltage. In pass-through mode, the output voltage follows input voltage. The SGM66099 exits down mode and enters into pass-through mode when $V_{IN} > V_{OUT} + 0.3V$.

The SGM66099 supports true shutdown function when it is disabled, which disconnects the load from the input supply to reduce the current consumption.

The SGM66099 offers both adjustable output voltage version and fixed output voltage versions. It is available in Green WLCSP-1.22×0.83-6B and TDFN-2×2-6AL packages.

FEATURES

- **Operating Input Voltage Range: 0.9V to 5.2V**
- **Ultra Low Quiescent Current**
  - **0.6μA Ultra Low I_Q into VOUT Pin**
  - **0.05μA Ultra Low I_Q into VIN Pin**
- **1.2MHz Fixed Frequency Operation**
- **Adjustable Output Voltage from 2.5V to 5.2V**
- **Fixed Output Voltage Versions Available**
- **Power-Save Mode for Improved Efficiency at Low Output Power**
- **Regulated Output Voltage in Down Mode**
- **True Disconnection During Shutdown**
- **Up to 75% Efficiency at 10μA Load with Fixed Output Voltage Version**
- **Up to 93% Efficiency from 10mA to 300mA Load**
- **Operating Ambient Temperature Ranges**
  - **Temperature Grade Y: -40℃ to +85℃**
  - **Temperature Grade X: -40℃ to +125℃**
- **Available in Green WLCSP-1.22×0.83-6B and TDFN-2×2-6AL Packages**

OVERSTRESS CAUTION

Stresses beyond those listed in Absolute Maximum Ratings may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Functional operation of the device at any conditions beyond those indicated in the Recommended Operating Conditions section is not implied.

ESD SENSITIVITY CAUTION

This integrated circuit can be damaged by ESD if you don’t pay attention to ESD protection. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

DETAILED DESCRIPTION

The SGM66099 synchronous step-up converter is designed for alkaline battery, coin-cell battery, Li-Ion or Li-Polymer battery powered systems, which requires long battery running time and tiny solution size. The SGM66099 can operate with a wide input voltage from 0.9V to 5.2V. It only consumes 0.65μA quiescent current and can achieve high efficiency under light load condition.

The SGM66099 operates in peak current mode with typical 1.3A peak switch current limit. The SGM66099 provides the true shutdown function and the load is completely disconnected from the input so as to minimize the leakage current. It also adopts down mode and pass-through operation when input voltage is close to or higher than the regulated output voltage. The SGM66099 is available in both adjustable and fixed output voltage versions. Adjustable version offers programmable output voltage for flexible applications while fixed versions offer minimal solution size and achieve up to 75% high efficiency under 10μA load.

Enable and Disable

When the EN pin is pulled to high, the SGM66099 is enabled. When the EN pin is pulled to low, the SGM66099 goes into shutdown mode. In shutdown mode, the device stops switching and the rectifying PMOS fully turns off, providing the completed disconnection between input and output. Less than 1μA input current is consumed in shutdown mode.

Startup and Low Supply Voltage Operation

The SGM66099 is able to start up with 0.9V input voltage with larger than 3kΩ load. However, if the load during startup is too heavy that the SGM66099 fails to charge the output voltage to above 2.2V, then it won’t be able to start up successfully.

The SGM66099 may not be shut down by pulling the EN to logic low when the supply voltage is below 0.85V.

Current Limit Operation

The SGM66099 employs cycle-by-cycle over-current protection (OCP) function. If the inductor peak current reaches the current limit threshold I_{LIM}, the main switch turns off so as to stop further increase of the input current. In this case the output voltage will decrease until the power balance between input and output is achieved. If the output drops below the input voltage, the SGM66099 enters into down mode. The peak current is still limited by I_{LIM} cycle-by-cycle in down mode. If the output drops below 2.2V, the SGM66099 enters into startup process again. In pass-through operation, current limit function is not enabled.

Output Short-to-Ground Protection

The SGM66099 starts to limit the switch current to about 200mA when the output voltage is below 2.2V. If short-to-ground condition occurs, switch current is limited at about 200mA. Once the short circuit is released, the SGM66099 goes back to soft start again and regulates the output voltage.

Over-Voltage Protection

SGM66099 has an output over-voltage protection (OVP) to protect the device in case that the external feedback resistor divider is wrongly connected. When the output voltage of the SGM66099 exceeds the OVP threshold of 5.8V, the device stops switching. Once the output voltage falls 0.1V below the OVP threshold, the device starts operating again.

Power-Save Mode Operation under Light Load Condition

The step-up converter of SGM66099 enters into power-save mode operation under light load condition.

Down Mode Regulation and Pass-Through Operation

The SGM66099 features down mode and pass-through operation when input voltage is close to or higher than output voltage.

DETAILED DESCRIPTION (continued)

In the down mode, output voltage is regulated at target value even when $V_{IN} > V_{OUT}$. The control circuit changes the behavior of the rectifying PMOS by pulling its gate to input voltage instead of to ground. In this way, the voltage drop across the PMOS is increasing as high as to regulate the output voltage. The power loss also increases in this mode, which needs to be taken into account for thermal consideration.

In the pass-through operation, the step-up converter stops switching. The rectifying PMOS constantly turns on and low-side switch constantly turns off. The output voltage is the input voltage minus the voltage drop across the DC resistance (DCR) of the inductor and the on-resistance of the rectifying PMOS.

With V_{IN} ramping up, the SGM66099 goes into down mode first when $V_{IN} > V_{OUT}$ - 100mV. It stays in down mode until $V_{IN} > V_{OUT}$ + 0.3V and then goes automatically into pass-through operation. In the pass-through operation, output voltage follows input voltage. The SGM66099 exits pass-through mode and goes back to down mode when V_{IN} ramps down to 101% of the target output voltage. It stays in down mode until input voltage falls 150mV below the output voltage, returning to boost operation.

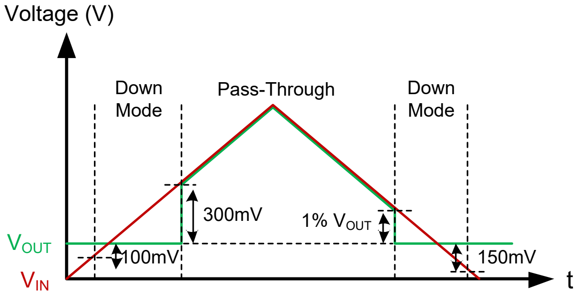

Figure 3. Down Mode and Pass-Through Operation

Thermal Shutdown

A thermal shutdown function is implemented to prevent damage caused by excessive heat and power dissipation. Once a temperature of typically +150°C is exceeded, the device is shut down. The device is released from shutdown automatically when the junction temperature decreases by 25℃.

APPLICATION INFORMATION

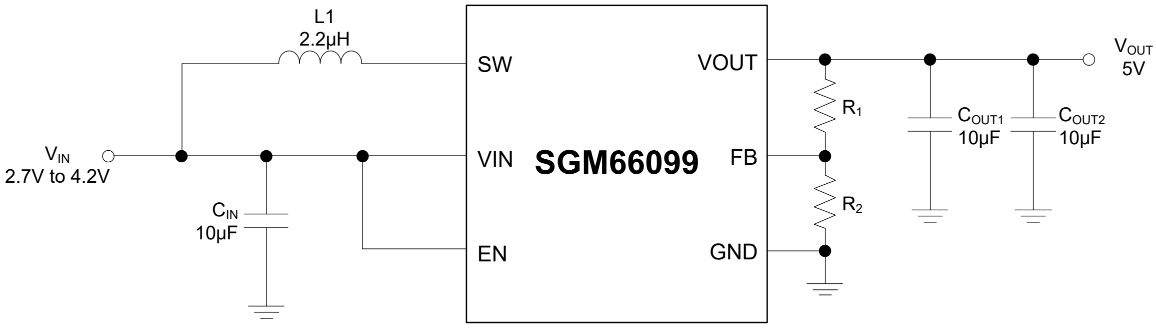

Figure 4. 5V Output Boost Converter

Design Requirements

A typical application example is the memory LCD, which normally requires 5V output as its bias voltage and only consumes less than 1mA current. The following design procedure can be used to select external component values for the SGM66099.

Table 1. Design Requirements

PARAMETERS	VALUES
Input Voltage	2.7V ~ 4.2V
Output Voltage	5V
Output Current	1mA
Output Voltage Ripple	±50mV

Programming the Output Voltage

There are two ways to set the output voltage of the SGM66099. For adjustable output voltage version, select the external resistor divider R_1 and R_2, as shown in Equation 1, and the output voltage is programmed to the desired value. When the output voltage is regulated, the typical voltage at the FB pin is V_{REF} of 1.0V.

$$V_{OUT} = V_{REF} \cdot \frac{R_1 + R_2}{R_2} \quad (1)$$

For fixed output voltage versions, the FB pin should be connected to GND or kept floating. The SGM66099 offers diverse fixed voltage versions.

In this example, 5V output is required to bias the memory LCD. For the best accuracy, the current following through R_2 should be 100 times larger than FB pin leakage current. Changing R_2 towards a lower value increases the robustness against noise injection. Changing R_2 towards higher values reduces the FB divider current for achieving the highest efficiency at low load currents. 1MΩ and 249kΩ resistors are selected for R_1 and R_2 in this example. High accuracy resistors are recommended for better output voltage accuracy.

Maximum Output Current

The maximum output capability of the SGM66099 is determined by the input to output ratio and the current limit of the step-up converter. It can be estimated by Equation 2.

$$I_{OUT(MAX)} = \frac{V_{IN} \cdot (I_{LIM} - \frac{I_{LH}}{2}) \cdot \eta}{V_{OUT}} \quad (2)$$

where η is the conversion efficiency, using 85% for estimation; I_{LH} is the current ripple value and I_{LIM} is the switch current limit.

Minimum input voltage, maximum boost output voltage and minimum current limit I_{LIM} should be used as the worst case condition for the estimation.

APPLICATION INFORMATION (continued)

Inductor Selection

Because the selection of the inductor affects steady state operation, transient behavior, and loop stability, the inductor is the most important component in power regulator design. There are three important inductor specifications, inductor value, saturation current, and DC resistance (DCR).

The device has been optimized to operate with inductance values between 1μH and 2.2μH. For best stability consideration, a 2.2μH inductor is recommended for V_{OUT} > 3.0V condition while choosing a 1μH inductor for applications under V_{OUT} ≤ 3.0V condition.

Table 2. List of Inductors

V_{OUT} (V)	Inductance (μH)	Saturation Current (A)	DC Resistance (MΩ)	Size (L × W × H)	Part Number	Manufacturer

	1.0	1.5	80	2.0 × 1.2 × 1.0	LQM21PN1R0MGH	muRata

Capacitor Selection

For best output and input voltage filtering, low ESR X5R or X7R ceramic capacitors are recommended.

The input capacitor minimizes input voltage ripple, suppresses input voltage spikes and provides a stable system rail for the device. An input capacitor value of 10μF is normally recommended to improve transient behavior of the regulator and EMI behavior of the total power supply circuit. A ceramic capacitor placed as close as possible to the VIN and GND pins of the device is recommended.

For the output capacitor of VOUT pin, small ceramic capacitors are recommended, placed as close as possible to the VOUT and GND pins of the device. If, for any reason, the application requires the use of large capacitors which cannot be placed close to the device, the use of a small ceramic capacitor with a capacitance value of 1μF in parallel to the large one is recommended. This small capacitor should be placed as close as possible to the VOUT and GND pins of the device.

From the power stage point of view, the output capacitor sets the corner frequency of the converter while the inductor creates a right-half-plane-zero. Consequently, with a larger inductor, a larger output capacitor must be used. The device has been optimized to operate with inductance values between 1μH and 2.2μH, so the minimal output capacitor value is 20μF (nominal value). Increasing the output capacitor makes the output ripple smaller in PWM mode.

When selecting capacitors, ceramic capacitor's derating effect under bias should be considered. Choose the right nominal capacitance by checking capacitor's DC bias characteristics. In this example, GRM188R60J106ME84D, which is a 10μF ceramic capacitor with high effective capacitance value at DC biased condition, is selected for V_{OUT} rail.

Layout

As for all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground paths. The input and output capacitor, as well as the inductor should be placed as close as possible to the device.

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

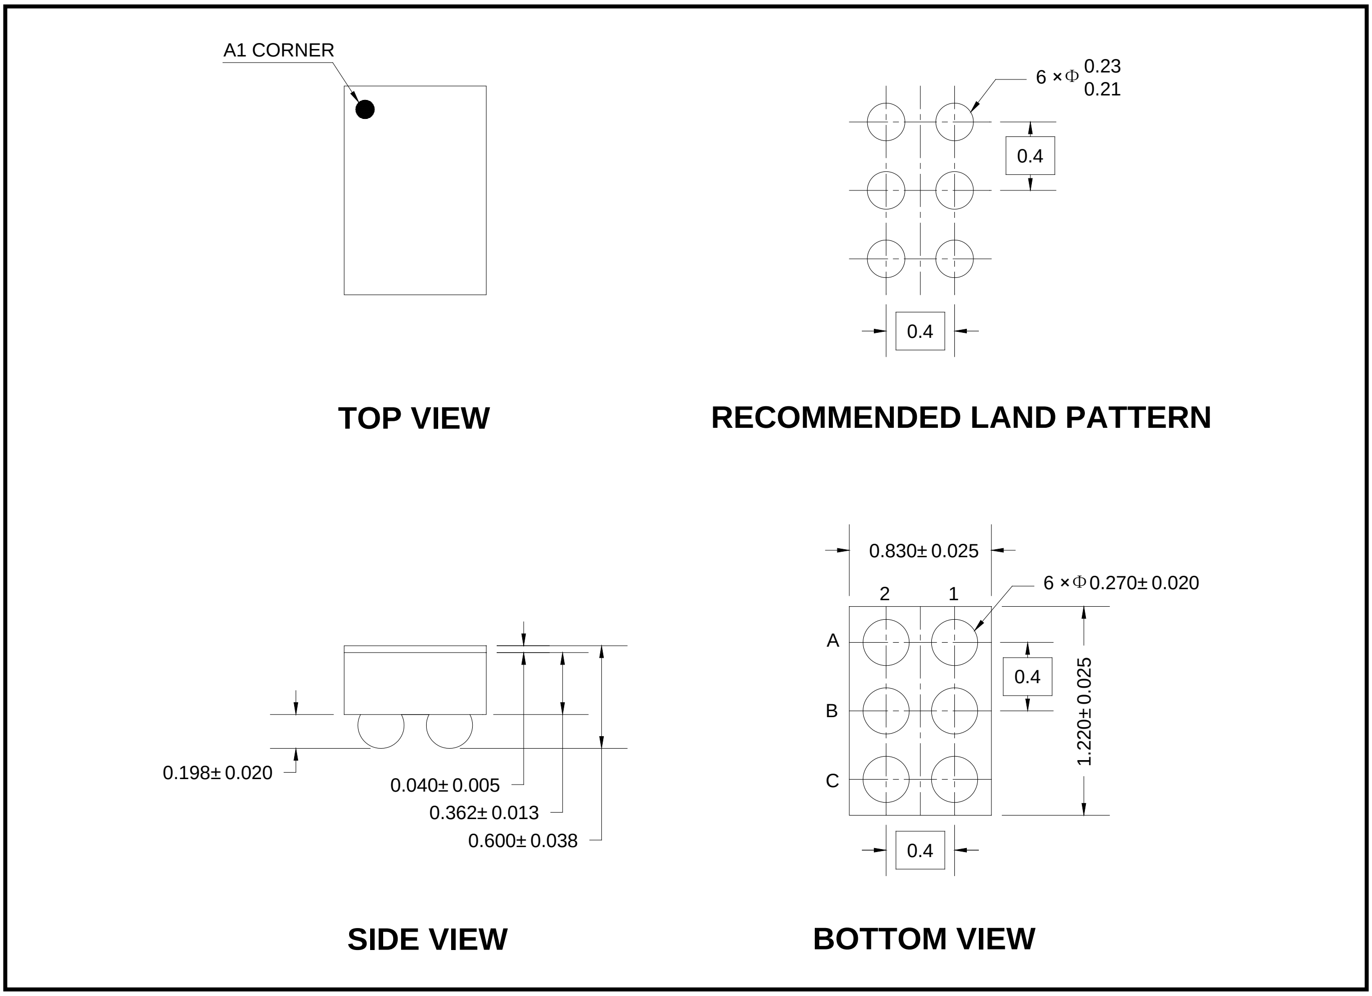
JULY 2019 – REV.A.1 to REV.A.2	Page
Added Temperature Grade X	All

APRIL 2019 – REV.A to REV.A.1	Page
Updated FB pin function	4, 13

Changes from Original (DECEMBER 2018) to REV.A	Page
Changed from product preview to production data	All

PACKAGE OUTLINE DIMENSIONS

WLCSP-1.22×0.83-6B



NOTE: All linear dimensions are in millimeters.
